

Open database manager website, and retrieve server's index.json file (businessID and business name) to generate a list of existing businesses on the website and save the index.json on local storage. Now, click on add a new business

New Business model:

Business name, address, phone (valid and format transfer to xxx xxx xxxx before saved to db), email (valid), map image, QR image, product, url slug (valid input with existing url slug to ensure unique), Owner first name, last name, phone (valid and format transfer to xxx xxx xxxx before saved to db), email (valid), address, username, password, payment methods, Account Valid Check (Active/Disable) and a button to save new business into business table of DB and display New Business Categories model. The button also generate a unique business ID in the DB business table

New Business Categories model:

An input of new categories name and a button to add the category to the Category table and generate a unique category ID in the Category table and also put the business ID of the new company into the Category table. Display newly added category nicely. Each saved category name can be edited right away on the list or deleted. The add button also active the cards model with refreshed category list into a drop down selection slot.

New Business Inventory/Cards model:

An input of new item card into the Cards table with selection of the category of the item, item name, description, price, unit of price, image select from url or from the image model list, video input from url or from video model list, featured on display or not and a button to add the card to the Cards table and generate a unique card ID in the Card table and also put the category ID of the selected category of the new business into the Card table. Display newly added card with card name in a list clickable to extend the card details for edit, delete and save

For the image and video input, please update the image and video table by generate unique image id / video id in the table with business id and save the image url. Use business id as principle of the table and list video and image in the images upload model / video upload model by adding the new image into list.

New Business image and video models are always there and it is open for user to add or delete images/ video from the list. And in the table use business id as the principle. Image and video must have a external url linkage to save server space.

After saved new business, the new business should be in the drop down menu of all listed business on the Database Manager page which is clickable to upload the business's information into business, categories and card models for further edition and save, and the new business ID and business name should be added to index.json file, and the new business model, categories model and card model should be saved into database.json in the save server.

Beside the add new business button, there should be a database display button to print database.json and index.json into a display tables for user to read on database manager page. These table only present when clicked the database display table for overall edition and disappear after click a cancel button

Display of the business website

After saved the new business profile and categories and cards and saved to database. The display website will be called as <https://communitybusinessservices.ca/wpgenerator?urlslug> format. So the display website's file name is wpgenerator.html and it will be upload on github server as a unique display. The business website could be visit publically by seraching the address above at SEO search engine and the valid check button on the business table of the business is active. For example, sunny bakery's business table has valid check as disabled then the data of this business cannot be load on wgenerator webpage. Only if it is active, the data is displayable as request.

Header should be eye catching with a login button for owner to access its dashboard hidden on the same page. Category list should be in nav bar and the drop down list of each category showing the first 10 cards. If more than 10 cards, use scroll bar to have browser read all items. Each card is clickable to display card information into main display arena. Featured items arean show only four items from randomly categories. Once browser selects a card or click on a category name on the nav bar, show only the selected category's item in the featured arena. If the selected featured item in the category is less than 4 leave the empty spot empty. Each featured card is clickable to present the item detail in the mian arena. The main arena should be bold and eye catching and consider to multiple device width. The footer should contain the business's contact, copyright to community business services and map image and qr image if there are.

If owner login successful, a dashboard model should appear at the bottom of the display menu. All data of this business only will be retrieved from database.json and copy to local storage for the owner to edit. There are business profile information editable (unique slug is not editable and business ID is not editable. Block them), category list editable and card list selectable to present selected card which is displayed and editable. After the owner changed information, he could submit all his business data on a temporary.json file for website master to prove before update on the website. And an email for reminder of update is sent to website master to check the temporary.json file. Business owner cannot edit database.json. Only website master can do it.
Problem: owner at their dashboard can insert image url to their product and the image is saved on temperary json in the image table and so does video.

Any uploaded video must have a youtube link and only video's youtube link is saved in video table.

You did well to retrieve information from database. Now the saving new business or changed information back to database from databaseManager is a problem. You have to be able to edit the database.json file which locate in the same folder of the databaseManager.html. And also update the index.json file in the same folder.
